## Teaching a Computer Not to Forget

One of the keys to unlocking artificial intelligence will be to figure out why biological brains are so good at remembering old skills—even when learning new things.

ADRIENNE LAFRANCE | APR 6 2015, 11:00 AM ET

- Imagine if every time you learned something new, you completely forgot how to do a thing you'd already learned.
- Finally figured out that taxi-hailing whistle? Now you can't tie your shoes anymore. Learn how to moonwalk; forget how to play the violin. Humans do forget skills, of course, but it usually happens gradually.
- 
-

"Researchers will need to solve this problem of catastrophic forgetting for us to get anywhere in terms of producing artificially intelligent computers and robots," said Jeff Clune, an assistant professor of computer science at the University of Wyoming. "Until we do, machines will be mostly one-trick ponies."

Catastrophic forgetting also stands in the way of one of the long-standing goals for artificial intelligence: to create computers that can compartmentalize different skills in order to solve diverse problems.

So what would it take for a computer brain to retain what it knows, even as it learns new things? That was the question Clune had when he and his colleagues set out to make an artificial brain act more like a human one. Their central idea: See if you can get a computer to organize—and preserve—what it knows within distinct modules of the brain,

rather than overwriting what it knows every time it learns something new.

"Biological brains exhibit a high degree of modularity, meaning they contain clusters of neurons with high degrees of connectivity within clusters, but low degrees of connectivity between clusters," the team explained [in a video](#) about their research, which was [published last week in the journal PLoS Computational Biology](#).

In humans and animals, brain modularity evolved as the optimal way to organize neural connections. That's because natural selection arranges the brain to minimize the costs associated with building, maintaining, and housing broader connections. "It is an interesting question as to how evolution solved this problem," Clune told me. "How did it figure out how to allow animals, including

us, to learn a new skill without overwriting the knowledge of a previously learned skill?"

In order to encourage modularity in a computer's brain, researchers incorporated what they call "connection costs"—essentially showing the computer that modularity is preferable. Then they measured the extent to which a computer remembered an old skill once it learned a new one.

And, indeed, modularity appears to help computers, like humans, compartmentalize what they know. Which means that modularity may be one of the keys to ending catastrophic forgetting. "This paper both illuminates how natural evolution may have solved this problem, and how machine intelligence may learn to overcome it as well: by having modular brains," Clune said. "I believe modularity will be one key focus going forward that will improve AI's ability to learn a variety of different skills, just like humans can."

"At present, there are more differences between human and computer intelligence than similarities," Clune said, "but we are slowly closing that gap."
